Tutorial Session 5

T-05: Mar - 06 - 2024, Wednesday, 19:00~19:50

T-12: Mar - 06 - 2024, Wednesday, 20:00~20:50

Problem 1

香港中文大學(深圳)理工学院
School of Science and Engineering

* A bicycle wheel has an initial angular velocity of **1.50 rad/s**.

Questions:

(a) If its angular acceleration is constant and equal to **0.300 rad/s²**, what is its angular velocity at **$t = 2.50$ s**?

(b) Through what angle has the wheel turned between **$t = 0$** and **$t = 2.50$ s**?

Solutions:

Identify: Apply the constant angular acceleration equations.

Set up: Let the direction of the wheel is rotating be positive.

Execute:

$$(a) \quad \omega_z = \omega_{0z} + \alpha_z t = 1.50 \text{ rad/s} + (0.300 \text{ rad/s}^2)(2.50 \text{ s}) = 2.25 \text{ rad/s}$$

$$(b) \quad \theta - \theta_0 = \omega_{0z} t + \frac{1}{2} \alpha_z t^2$$
$$= (1.50 \text{ rad/s})(2.50 \text{ s}) + \frac{1}{2} (0.300 \text{ rad/s}^2)(2.50 \text{ s})^2 = 4.69 \text{ rad}$$

QED.

Problem 2

香港中文大學(深圳)理工学院
School of Science and Engineering

* Rotating Wheel:

Sketch a wheel lying in the plane of your paper and rotating counterclockwise. Choose a point on the rim and draw a vector \vec{r} from the center of the wheel to that point.

Question (a):

(a) What is the direction of angular velocity $\vec{\omega}$?

Solution (a):

For a counterclockwise rotation, the direction of $\vec{\omega}$ is upward, perpendicular to the paper.

Problem 2

香港中文大學(深圳)理工学院
School of Science and Engineering

Question (b):

(b) Check that the velocity \vec{v} of the point can be written as $\vec{v} = \vec{\omega} \times \vec{r}$. Remember to show that this is true for both the direction and magnitude.

Hint:

There are two methods you can use.

1. Simply use the *right-hand rule* to determine the direction of the cross product.
2. Use the mathematical expression of the cross product in terms of unit vectors.

Solution (b):

Use the *Right-Hand Rule* to find the direction \vec{v} and $\vec{\omega} \times \vec{r}$ are the same (the upward direction crossed into the outward radial direction is counterclockwise tangential direction), and their amplitude are $v = \omega r$, therefore $\vec{v} = \vec{\omega} \times \vec{r}$.

Problem 2

香港中文大學(深圳)理工学院
School of Science and Engineering

Question (c):

(c) Check that the radial acceleration of the point is $\vec{a}_{rad} = \vec{\omega} \times \vec{v} = -\omega^2 \vec{r}$. Remember to show that this is true for both the direction and magnitude.

Hint:

There are two methods you can use.

1. Simply use the ***right-hand rule*** to determine the direction of the cross product.
2. Apply the following mathematical identity

$$\vec{A} \times (\vec{B} \times \vec{C}) = (\vec{A} \cdot \vec{C})\vec{B} - (\vec{A} \cdot \vec{B})\vec{C}$$

and show that $\vec{\omega} \times (\vec{\omega} \times \vec{r}) = -\omega^2 \vec{r}$.

Problem 2

香港中文大學(深圳)理工学院
School of Science and Engineering

Solution (c):

Geometrically, $\vec{\omega}$ is perpendicular to \vec{v} and so $\vec{\omega} \times \vec{v}$ has the magnitude of $a_{rad} = \omega v = \omega^2 r$. From the *Right-Hand Rule*, the upward direction crossed into the counterclockwise direction is inward, namely, the direction of \vec{a}_{rad} . Algebraically,

$$\begin{aligned}\vec{a}_{rad} &= \vec{\omega} \times \vec{v} = \vec{\omega} \times (\vec{\omega} \times \vec{r}) \\ &= (\vec{\omega} \cdot \vec{r})\vec{\omega} - (\vec{\omega} \cdot \vec{\omega})\vec{r} = -\omega^2 \vec{r}\end{aligned}$$

where we have used the fact $\vec{\omega} \cdot \vec{r} = 0$.

Question (d):

Given the mass of the thin-rimmed wheel m , compute the moment of inertia of this wheel.

Solution (d):

The momentum of inertial $I = \int dmr^2 = mr^2$, since all the mass of the wheel is distributed on the rim with distance r from the center.

QED.

Problem 3

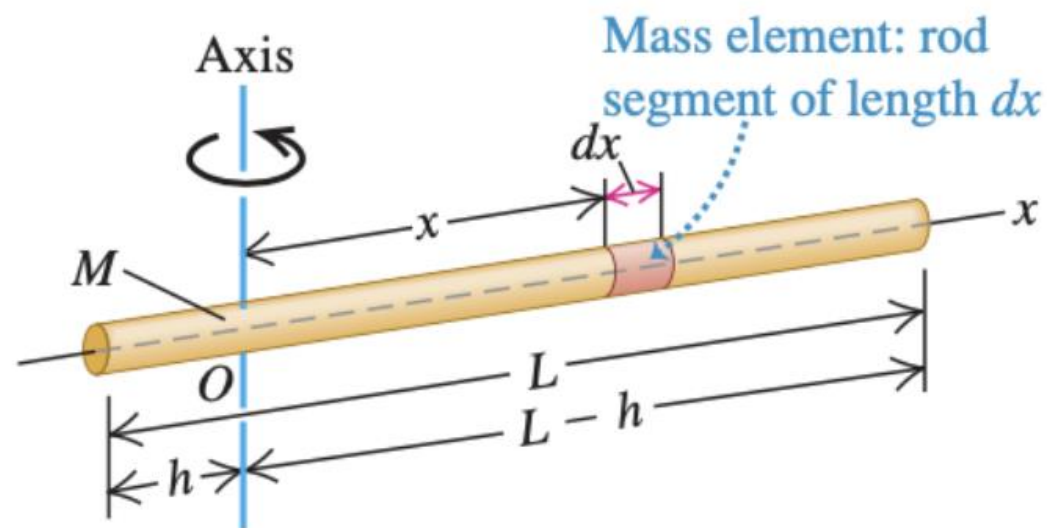

香港中文大學(深圳)理工学院
School of Science and Engineering

* * A Rotating, Uniform Thin Rod:

The figure below shows a slender uniform rod with mass M and length L . It might be a baton held by a twirler in a marching band (less the rubber end caps).

A thin rod with an axis through O .

Problem 3

香港中文大學(深圳)理工学院
School of Science and Engineering

Question (a):

Use integration to compute its moment of inertia about an axis through O , at an arbitrary distance h from one end.

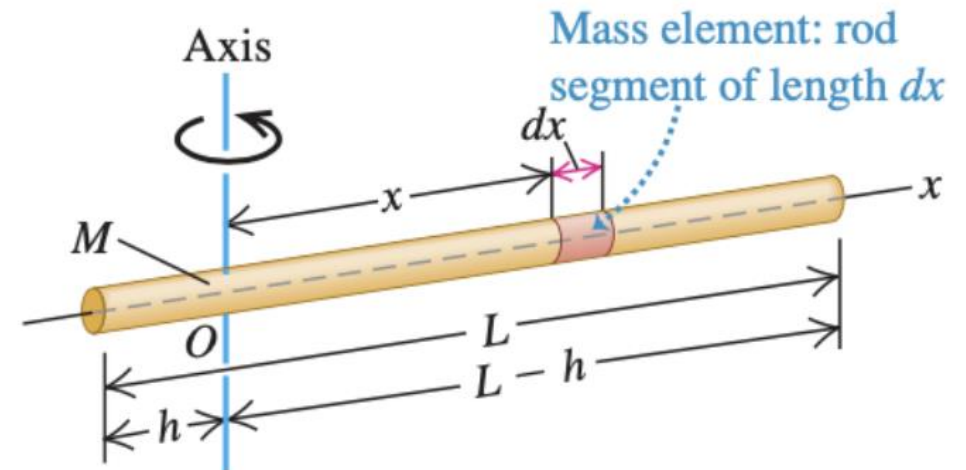

Solution (a):

The rod is a continuous distribution of mass, so we use integration to find the rotational inertia. Let us choose a small element of mass, namely, a short section of rod with length dx at a distance x from point O as shown in the figure.

Since the rod is uniform, thus $dm/M = dx/L$ so $dm = \frac{M}{L} dx$. By definition, one finds the moment of inertia

$$\begin{aligned} I &= \int x^2 dm = \frac{M}{L} \int_{-h}^{L-h} x^2 dx \\ &= \left[\frac{M}{L} \left(\frac{x^3}{3} \right) \right]_{-h}^{L-h} = \frac{M}{3} (L^2 - 3Lh + 3h^2) \end{aligned}$$

A thin rod with an axis through O .

Problem 3

Question (b):

Check the plausibility of the above answer for I . Set $h = 0$ or $h = L/2$, and check whether it agrees with the known answers or not.

Use parallel-axis theorem ($I = I_{CM} + Md^2$) to compute the rotational inertia I again.

Solution (b):

If the axis is at the left end, then $h = 0$ and $I = \frac{1}{3}ML^2$. If the axis passes through the center, then $h = L/2$ and $I = \frac{1}{12}ML^2$.

Both are in agreement with the known results. Furthermore, use parallel-axis theorem, one gets

$$I = I_{CM} + Md^2 = \frac{1}{12}ML^2 + M\left(\frac{L}{2} - h\right)^2 = \frac{M}{3}(L^2 - 3Lh + 3h^2),$$

which is the same as the result in part (a).

Problem 3

香港中文大學(深圳)理工学院
School of Science and Engineering

Question (c):

Initially the rod is at rest. It is given a constant angular acceleration of magnitude α around the axis through O . Find how much work is done on the rod in a time t .

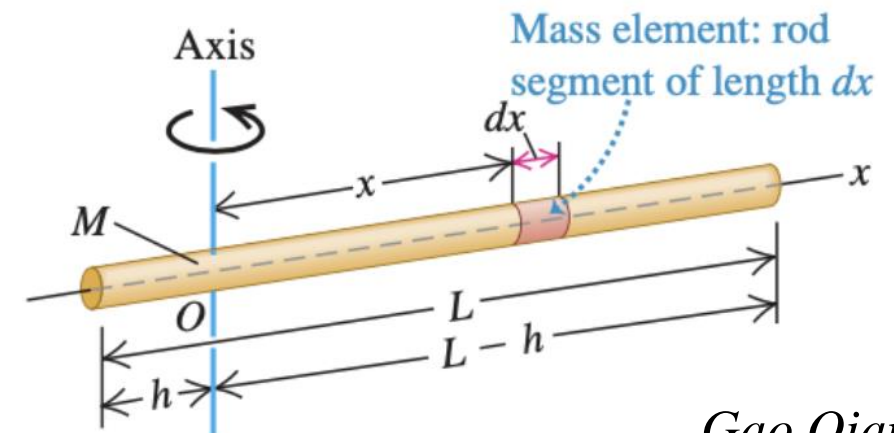

Solution (c):

Work equals the increase of kinetic energy, thus

$$W = \frac{1}{2} I \omega^2 = \frac{M}{6} (L^2 - 3Lh + 3h^2) (\alpha t)^2$$

where $\omega = \alpha t$.

A thin rod with an axis through O .

Gao Qian

Problem 3

香港中文大學(深圳)理工学院
School of Science and Engineering

Question (d):

At time t , what is the magnitude of the total linear acceleration of the point on the rod farthest from the axis? (Suppose $L - h > h$)

Hint: Don't forget the acceleration includes the radial and tangential parts.

Solution (d):

The total acceleration

$$a = \sqrt{a_{\perp}^2 + a_{\parallel}^2} = \alpha(L - h)\sqrt{1 + \alpha^2 t^4}$$

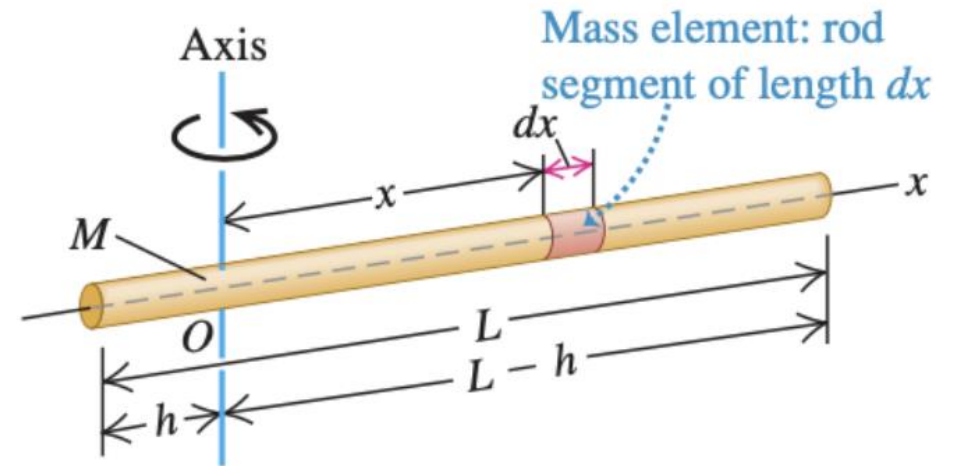

with

$$a_{\perp} = \omega^2 r = (\alpha t)^2 (L - h)$$

and

$$a_{\parallel} = \alpha r = \alpha(L - h)$$

A thin rod with an axis through O .

QED.

Problem 4

香港中文大學(深圳)理工学院
School of Science and Engineering

* Energy from the Moon?

Suppose that some time in the future we decide to tap the moon's rotational energy for use on earth. In addition to the usual astronomical data ($M = 7.35 \times 10^{22} \text{ kg}$ and $R = 1.74 \times 10^6 \text{ m}$), you may need to know that the moon spins on its axis once every **27.3** days. Assume that the moon is uniform throughout.

Questions:

- (a) How much total energy could we get from the moon's rotation?
- (b) The world presently uses about $4.00 \times 10^{20} \text{ J}$ of energy per year. If in the future the world uses five times as much energy yearly, for how many years would the moon's rotation provide us energy?

Problem 4

香港中文大學(深圳)理工学院
School of Science and Engineering

Question (a): How much total energy could we get from the moon's rotation?

Solution (a):

Identify: $K = \frac{1}{2} I \omega^2$. Use Table 9.2 to calculate I .

Set up: $I = \frac{2}{5} M R^2$. For the moon, $M = 7.35 \times 10^{22} \text{ kg}$ and $R = 1.74 \times 10^6 \text{ m}$.

The moon moves through $1 \text{ rev} = 2\pi \text{ rad}$ in 27.3 d . $1 \text{ d} = 8.64 \times 10^4 \text{ s}$.

Execute:

$$I = \frac{2}{5} (7.35 \times 10^{22} \text{ kg}) (1.74 \times 10^6 \text{ m})^2 = 8.90 \times 10^{34} \text{ kg} \cdot \text{m}^2$$

$$\omega = \frac{2\pi \text{ rad}}{(27.3 \text{ d})(8.64 \times 10^4 \text{ s/d})} = 2.66 \times 10^{-6} \text{ rad/s}$$

$$K = \frac{1}{2} I \omega^2 = \frac{1}{2} (8.90 \times 10^{34} \text{ kg} \cdot \text{m}^2) (2.66 \times 10^{-6} \text{ rad/s})^2 = 3.15 \times 10^{23} \text{ J}$$

Problem 4

Question (b): The world presently uses about 4.00×10^{20} J of energy per year. If in the future the world uses five times as much energy yearly, for how many years would the moon's rotation provide us energy?

Solution (b):

$$\frac{3.15 \times 10^{23} \text{ J}}{5(4.0 \times 10^{20} \text{ J})} = 158 \text{ years}$$

Considering the expense involved in tapping the moon's rotational energy, this does not seem like a worthwhile scheme for only **158 years** worth of energy.

Evaluate:

The moon has a very large amount of kinetic energy due to its motion. The earth has even more, but changing the rotation rate of the earth would change the length of a day.

QED.

Problem 5

香港中文大學(深圳)理工学院
School of Science and Engineering

* A roller in a printing press turns through an angle $\theta(t)$ given by $\theta(t) = \gamma t^2 - \beta t^3$, where $\gamma = 3.20 \text{ rad/s}^2$ and $\beta = 0.500 \text{ rad/s}^3$.

Questions:

- (a) Calculate the angular velocity of the roller as a function of time.
- (b) Calculate the angular acceleration of the roller as a function of time.
- (c) What is the maximum positive angular velocity, and at what value of t does it occur?

Problem 5

香港中文大學(深圳)理工学院
School of Science and Engineering

Question (a):

Calculate the angular velocity of the roller as a function of time.

Solution (a):

$$\omega_z(t) = \frac{d\theta}{dt} = \frac{d(\gamma t^2 - \beta t^3)}{dt} = 2\gamma t - 3\beta t^2$$

Question (b):

Calculate the angular acceleration of the roller as a function of time.

Solution (b):

$$\alpha_z(t) = \frac{d\omega_z}{dt} = \frac{d(2\gamma t - 3\beta t^2)}{dt} = 2\gamma - 6\beta t$$

Problem 5

香港中文大學(深圳) 理工学院
School of Science and Engineering

Question (c):

What is the maximum positive angular velocity, and at what value of t does it occur?

Solution (c):

The maximum angular velocity occurs when $\alpha_z = 0$.

$$2\gamma - 6\beta t = 0 \quad \text{implies} \quad t = \frac{2\gamma}{6\beta} = \frac{\gamma}{3\beta} = \frac{3.20 \text{ rad/s}^2}{3(0.500 \text{ rad/s}^3)} = 2.133 \text{ s}$$

At this t ,

$$\begin{aligned}\omega_z &= 2\gamma t - 3\beta t^2 \\ &= 2(3.20 \text{ rad/s}^2)(2.133 \text{ s}) - 3(0.500 \text{ rad/s}^3)(2.133 \text{ s})^2 = 6.83 \text{ rad/s}\end{aligned}$$

The maximum positive angular velocity is **6.83 rad/s** and it occurs at 2.13 s.

Evaluate: For large t both ω_z and α_z are negative and ω_z increases in magnitude. In fact, $\omega_z \rightarrow -\infty$ at $t \rightarrow \infty$. So the answer in (c) is not largest angular speed, just the largest positive angular velocity.

QED.

Gao Qian

Problem 6

香港中文大學(深圳)理工学院
School of Science and Engineering

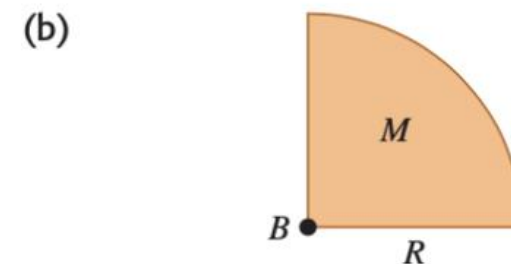

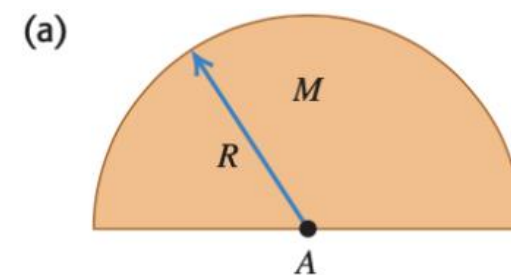

* A uniform disk of radius R is cut in half so that the remaining half has mass M (Fig. a).

Questions:

(a) What is the moment of inertia of this half about an axis perpendicular to its plane through point A ?

(b) Why did your answer in part (a) come out the same as if this were a complete disk of mass M ?

(c) What would be the moment of inertia of a quarter disk of mass M and radius R about an axis perpendicular to its plane passing through point B (Fig. b)?

Problem 6

Solutions:

Identify: Compare this object to a uniform disk of radius R and mass $2M$.

Set up: With an axis perpendicular to the round face of the object at its center, I for a uniform disk is the same as for a solid cylinder.

Execute:

- (a) The total I for a disk of mass $2M$ and radius R , $I = \frac{1}{2}(2M)R^2 = MR^2$. Each half of the disk has the same I , so for the half-disk, $I = \frac{1}{2}MR^2$.
- (b) The same mass M is distributed the same way as a function of distance from the axis.
- (c) The same method as in part (a) says that I for a quarter-disk of radius R and mass M is half that of a half-disk of radius R and mass $2M$, so $I = \frac{1}{2}(\frac{1}{2}[2M]R^2) = \frac{1}{2}MR^2$.

Evaluate: I depends on how the mass of the object is distributed relative to the axis, and this is the same for any segment of a disk.

QED.

Problem 7

****** A thin, uniform rod is bent into a square of side length a . If the total mass is M , find the moment of inertia about an axis through the center and perpendicular to the plane of the square. (**Hint:** Use the *parallel-axis theorem*.)

Solution:

(1) Apply the *parallel-axis theorem* to each side of the square.

(2) Each side has length a and mass $M/4$, and the moment of inertia of each side about an axis perpendicular to the side and through its center is

$$\frac{1}{12} \left(\frac{M}{4} a^2 \right) = \frac{1}{48} M a^2$$

(3) The moment of inertia of each side about the axis through the center of the square is, from the *parallel-axis theorem*,

$$I_{cm} + md^2 = \frac{1}{48} M a^2 + \frac{M}{4} \left(\frac{a}{2} \right)^2 = \frac{M a^2}{12}$$

Problem 7

Solution:

The total moment of inertia is the sum of the contributions from the four sides, namely,

$$I = \frac{Ma^2}{12} \times 4 = \frac{Ma^2}{3}$$

(4) **Plausibility check**: If all the mass of a side were concentrated at its center, a distance $a/2$ from the axis, we would have

$$4 \frac{M}{4} \left(\frac{a}{2} \right)^2 = \frac{Ma^2}{4}$$

If all the mass was divided equally among the four corners of the square, a distance $a/\sqrt{2}$ from the axis, we would have

$$4 \frac{M}{4} \left(\frac{a}{\sqrt{2}} \right)^2 = \frac{Ma^2}{2}$$

The actual $I = 1/3 Ma^2$ is between these two values.

QED.

Problem 8

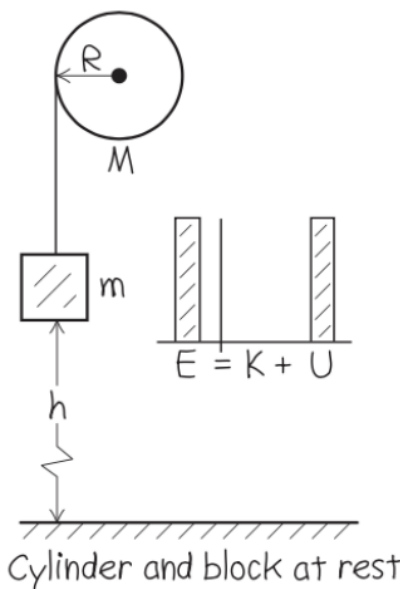

香港中文大學(深圳)理工学院
School of Science and Engineering

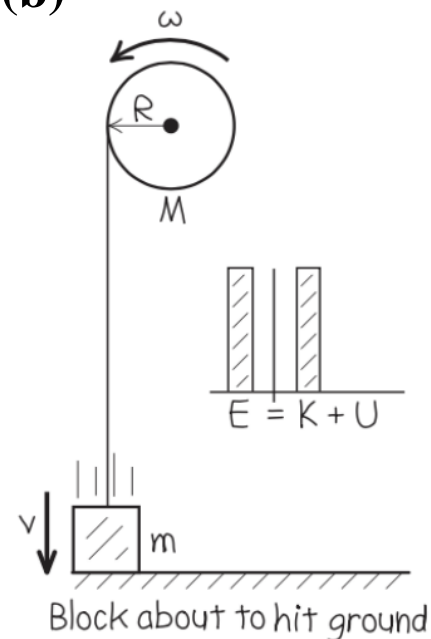

** An unwinding cable:

We wrap a light, non-stretching cable around a solid cylinder with mass M and radius R . The cylinder rotates with negligible friction about a stationary horizontal axis. We tie the free end of the cable to a block of mass m and release the block from rest at a distance h above the floor. As the block falls, the cable unwinds without stretching or slipping. Find expressions for the speed of the falling block and the angular speed of the cylinder as the block strikes the floor.

(a)

(b)

Problem 8

Solution:

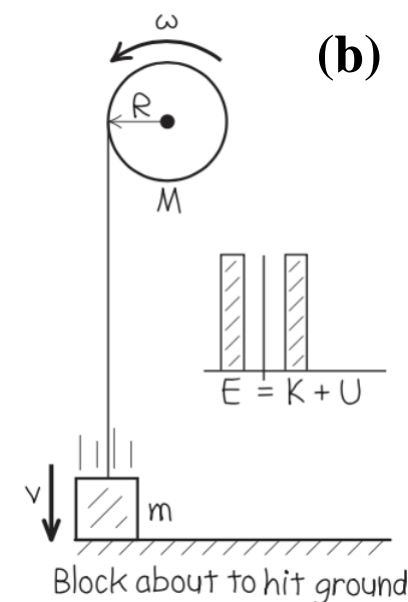

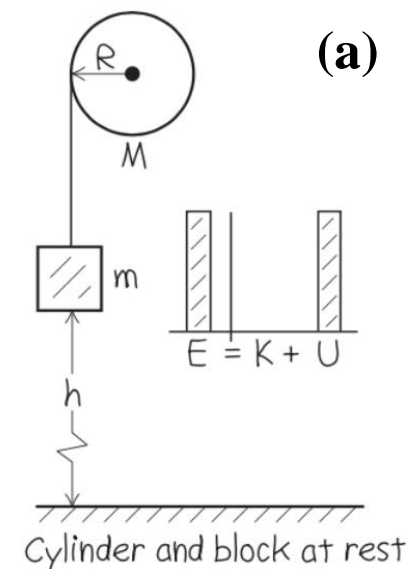

(1) Although there is friction between the cable and the solid cylinder, there is no motion of the cable relative to the cylinder and no mechanical energy is lost in frictional work because the cable does NOT slip.

(2) Only gravity does work, and mechanical energy is conserved.

(3) We assume that the cable is massless, thus we know that all the change of potential energy is converted to the kinetic energy of the block and the cylinder

$$mgh = \frac{1}{2}mv^2 + \frac{1}{2}I\omega^2$$

with $I = \frac{1}{2}MR^2$.

Problem 8

Solution:

(4) Also, $v = R\omega$ since the cable does not slip and thus the speed of the falling block must be equal to the tangential speed at the outer surface of the cylinder. Solving for v gives

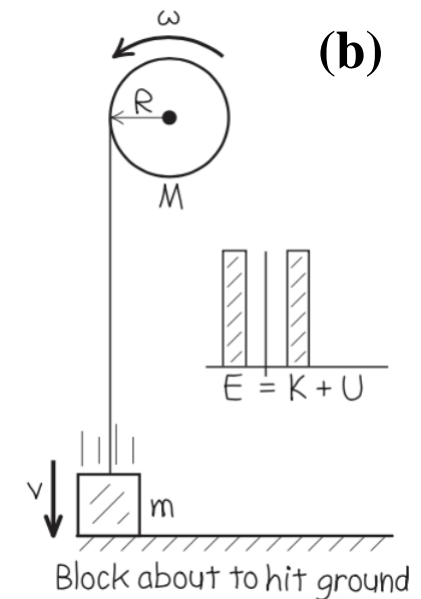

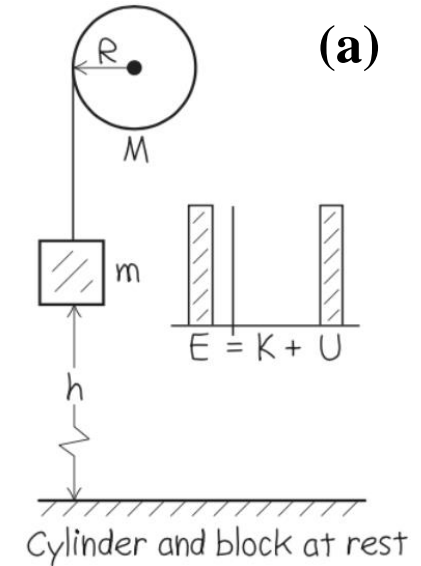

$$v = \sqrt{\frac{2gh}{1 + I/mR^2}} = \sqrt{\frac{2gh}{1 + M/2m}}$$

and $\omega = v/R$.

(5) When M is much larger than m , v is very small; when M is much smaller than m , v becomes $\sqrt{2gh}$, the speed of a body that falls freely from height h .

(6) Both of these results are as we would expect.

QED.

Problem 9

**** Find the rotational inertia of a solid and uniform cylinder about its central axis.**

Solution:

(1) Let L be the length of the cylinder and divide the cylinder into thin cylindrical shells of inner radius r and outer radius $r + dr$.

(2) Then the mass of the thin shell is then $dm = \rho dV = \rho(2\pi r dr)L$. The rotational inertia is

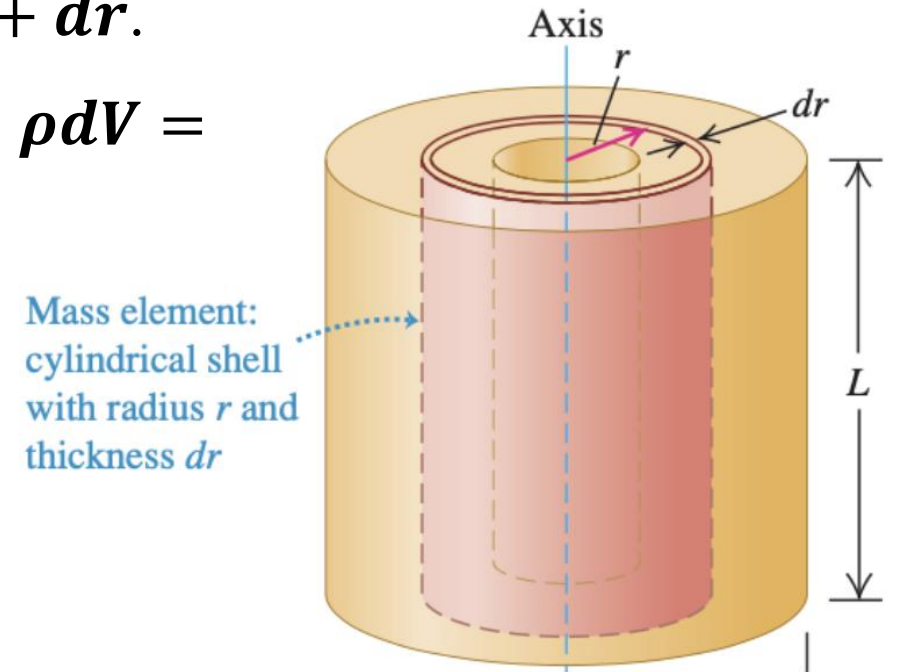

$$I = \int r^2 dm = 2\pi\rho L \int_0^R r^3 dr = \frac{2\pi\rho LR^4}{4}$$

(3) Next, relate M to ρ as follows

$$M = \int dm = 2\pi\rho L \int_0^R r dr = \frac{2\pi\rho LR^2}{2}$$

(4) Taking the ratio of the above results, one finds $I = \frac{1}{2}MR^2$.

QED.

Problem 10

香港中文大學(深圳)理工学院
School of Science and Engineering

* * * A cylinder with radius R and mass M has density that increases linearly with distance r from the cylinder axis, $\rho = \alpha r$, where α is a positive constant.

Questions:

- (a) Calculate the moment of inertia of the cylinder about a longitudinal axis through its center in terms of M and R .
- (b) Is your answer greater or smaller than the moment of inertia of a cylinder of the same mass and radius but of uniform density? Explain why this result makes qualitative sense.

Problem 10

Solution (a):

(1) Let L be the length of the cylinder and divide the cylinder into thin cylindrical shells of inner radius r and outer radius $r + dr$.

(2) Then the mass of the thin shell is then $dm = \rho dV = \rho(2\pi r dr)L = 2\pi\alpha L r^2 dr$.

(3) The rotational inertia is:

$$I = \int r^2 dm = 2\pi\alpha L \int_0^R r^4 dr = \frac{2\pi\alpha L R^5}{5}$$

(4) Next, relate M to α as follows:

$$M = \int dm = 2\pi\alpha L \int_0^R r^2 dr = \frac{2\pi\alpha L R^3}{3}$$

(5) Taking the ratio of the above results, one finds $I = \frac{3}{5}MR^2$.

Problem 10

香港中文大學(深圳)理工学院
School of Science and Engineering

* * * A cylinder with radius R and mass M has density that increases linearly with distance r from the cylinder axis, $\rho = \alpha r$, where α is a positive constant.

Question (b):

Is your answer greater or smaller than the moment of inertia of a cylinder of the same mass and radius but of uniform density? Explain why this result makes qualitative sense.

Solution (b):

(1) For a cylinder of uniform density $I = \frac{1}{2}MR^2$, the answer in (a) is larger than this.

(2) Since the density increases with distance from the axis the cylinder in (a) has more mass farther from the axis than for a cylinder of uniform density.

QED.
