## **Tutorial Session**

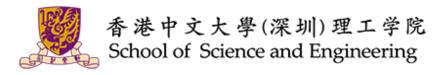

## PHY 1001: Mechanics

### Tutorial Session 13

T-05: May - 08 - 2024, Wednesday, 19:00~19:50

T-12: May - 08 - 2024, Wednesday, 20:00~20:50

### \* Speed of sound waves

#### **Questions:**

- (a) In a liquid with density  $1300 \text{ kg/m}^3$ , longitudinal waves with frequency 400 Hz are found to have wavelength 8.00 m. Calculate the bulk modulus of the liquid.
- (b) A metal bar with a length of 1.50 m has density  $6400 \text{ kg/m}^3$ . Longitudinal sound waves take  $3.9 \times 10^{-4} \text{ s}$  to travel from one end of the bar to the other. What is Young's modulus for this metal?

#### **Solution:**

(a) For waves in general,  $v = f\lambda$ . For a wave in the liquid,  $v = \sqrt{B/\rho}$  with B the bulk modulus and  $\rho$  the density. Using these two formulas, one gets

$$B = v^2 \rho = (f\lambda)^2 \rho = 1.33 \times 10^{10} \text{ Pa}.$$

(b) For wave velocity in general,  $\mathbf{v} = \Delta L/\Delta t$ . For a wave in the metal,  $\mathbf{v} = \sqrt{Y/\rho}$  with Y the Young's modulus and  $\rho$  the density. Using these two formulas, one gets

$$Y = v^2 \rho = (\Delta L/\Delta t)^2 \rho = 9.47 \times 10^{10} \text{ Pa}.$$

### \* \* Standing Sound Waves and Normal Modes

#### **Questions:**

- (a) Standing sound waves are produced in a pipe that is **1.20 m** long. For the fundamental mode (i.e. first harmonic) and first two overtones (i.e., the second and third harmonics), determine the locations along the pipe (measured from the left end) of the displacement nodes and the pressure nodes if the pipe is open at both ends.
- (b) What if the pipe is closed at the left end and open at the right end?
- (c) Singing in the Shower. A pipe closed at both ends can have standing waves inside of it, but you normally don't hear them because little of the sound can get out. But you can hear them if you are inside the pipe, such as someone singing in the shower. Show that the wavelengths of standing waves in a pipe of length L that is closed at both ends are  $\lambda_n = 2L/n$  and the frequencies are given by  $f_n = nv/(2L)$ , where  $n = 1, 2, 3, \cdots$ . Modeling the shower as a pipe, find the frequency of the fundamental and the first two over-tones for a shower 2.50 m tall. Are these frequencies audible?

Gao Qian

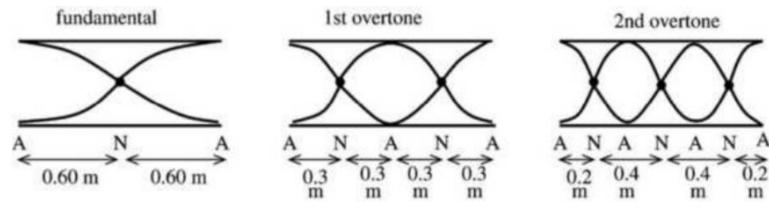

### **Identify** and **Set Up**:

- > An open end is a displacement antinode and a closed end is a displacement node.
- > Sketch the standing wave pattern and use the sketch to relate the node-to-antinode distance to the length of the pipe.
- ➤ A displacement node is a pressure antinode and a displacement antinode is a pressure node.

#### **Execute:**

(a) The placement of the displacement nodes and antinodes along the pipe is as sketched in **Figure 16.25a**. The open ends are displacement antinodes.

**Figure 16.25a** 

Location of the displacement nodes (N) measured from the left end:

fundamental 0.60 m

**lst** overtone **0.30 m**, **0.90 m** 

2nd overtone 0.20 m, 0.60 m, 1.00 m

Location of the pressure nodes (displacement antinodes (A)) measured from the left end:

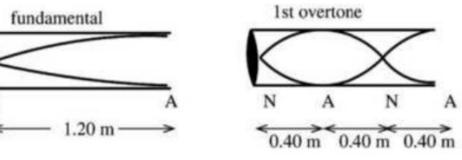

fundamental 0, 1.20 m

**lst** overtone **0**, **0.60** m, **1.20** m

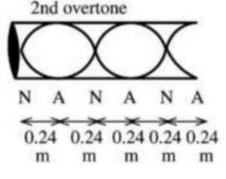

2nd overtone 0, 0.40 m, 0.80 m, 1.20 m

(b) The open end is a displacement antinode and the closed end is a displacement node. The placement of the displacement nodes and antinodes along the pipe is sketched in **Figure** 

16.25b.

**Figure 16.25b** 

Gao Qian

Location of the displacement nodes (N) measured from the closed end:

fundamental 0

1st overtone 0, 0.80 m

2nd overtone 0, 0.48 m, 0.96 m

Location of the pressure nodes (displacement antinodes (A)) measured from closed end:

fundamental 1.20 m

**lst** overtone **0.40 m**, **1.20 m** 

2nd overtone 0.24 m, 0.72 m, 1.20 m

Evaluate: The node-to-node or antinode-to-antinode distance is  $\lambda/2$ . For the higher overtones the frequency is higher and the wavelength is smaller.

**Identify:** There must be a node at each end of the pipe. For the fundamental there are no additional nodes and each successive overtone has one additional node.  $v = f\lambda$ .

Set Up: v = 344 m/s. The node to node distance is  $\lambda/2$ .

#### **Solution:**

(a)  $\lambda_1/2 = L$  so  $\lambda_1 = 2L$ . Each successive overtone adds an additional  $\lambda/2$  along the pipe, so

$$n\left(\frac{\lambda_n}{2}\right) = L$$
 and  $\lambda_n = \frac{2L}{n}$ , where  $n = 1, 2, 3, \dots$   $f_n = \frac{v}{\lambda_n} = \frac{nv}{2L}$ .

(b) 
$$f_1 = \frac{v}{2L} = \frac{344 \text{ m/s}}{2(2.50 \text{ m})} = 68.8 \text{ Hz.}$$
  $f_2 = 2f_1 = 138 \text{ Hz.}$   $f_3 = 3f_1 = 206 \text{ Hz.}$ 

All three of these frequencies are audible.

(c) Derive  $\lambda_n = 2L/n$  and  $f_n = nv/(2L)$ , then find  $f_1 = 68.8$  Hz,  $f_2 = 138$  Hz, and  $f_3 = 206$  Hz. Yes, they are within the range of the audible sound frequency (audible range) from about 20 Hz to 20,000 Hz.

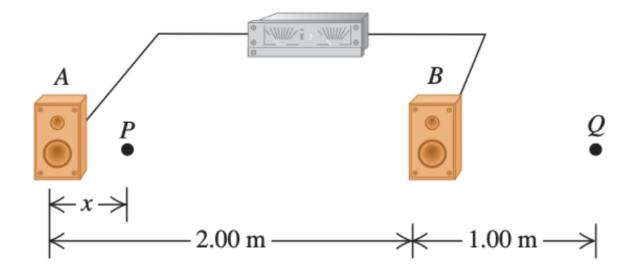

Evaluate: A pipe of length L closed at both ends has the same standing wave wavelengths, frequencies and nodal patterns as for a string of length L that is fixed at both ends.

\* \* Two loudspeakers, **A** and **B** (Figure below), are driven by the same amplifier and emit sinusoidal waves in phase. Speaker **B** is **2.00** m to the right of speaker **A**. Consider point **Q** along the extension of the line connecting the speakers, **1.00** m to the right of speaker **B**. Both speakers emit sound waves that travel directly from the speaker to point **Q**. (a) (b)

#### **Questions:**

- (a) What is the lowest frequency for which constructive interference occurs at point  $\mathbf{Q}$ ?
- (b) What is the lowest frequency for which destructive interference occurs at point  $\mathbf{Q}$ ?

#### **Solution (a):**

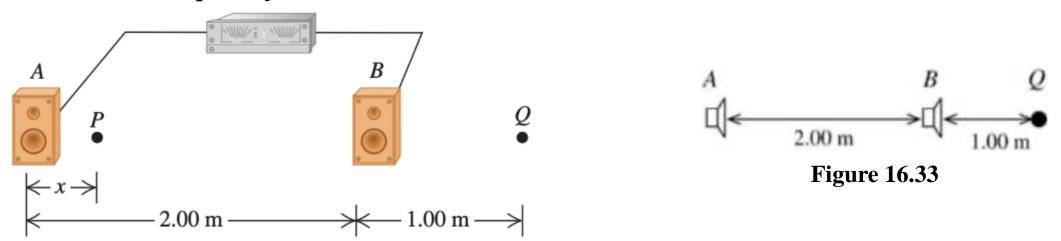

### **Identify** and **Set Up**:

Path difference from points A and B to point Q is 3.00 m - 1.00 m = 2.00 m, as shown in Figure 16.33. Constructive interference implies path difference  $= n\lambda$ ,  $n = 1, 2, 3, \cdots$ 

**Execute:** 2.00 m = 
$$n\lambda$$
 so  $\lambda = 2.00$  m/ $n$ 

$$f = \frac{v}{\lambda} = \frac{nv}{2.00 \text{ m}} = \frac{n(344 \text{ m/s})}{2.00 \text{ m}} = n(172 \text{ Hz}), \qquad n = 1, 2, 3, \dots$$

The lowest frequency for which constructive interference occurs is 172 Hz.

香港中文大學(深圳)理工学院 School of Science and Engineering

### **Solution (b):**

**Identify** and **Set Up**:

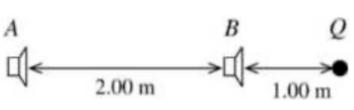

Destructive interference implies path difference  $(n/2)\lambda$ ,  $n=1,3,5,\cdots$ 

**Execute:** 2.00 m = 
$$(n/2)\lambda$$
 so  $\lambda = 4.00$  m/ $n$ 

$$f = \frac{v}{\lambda} = \frac{nv}{4.00 \text{ m}} = \frac{n(344 \text{ m/s})}{4.00 \text{ m}} = n(86 \text{ Hz}), \qquad n = 1, 3, 5, \dots$$

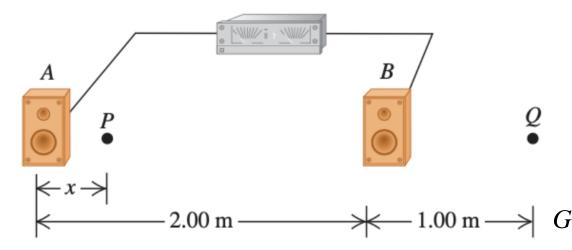

The lowest frequency for which destructive interference occurs is **86 Hz**.

Evaluate: As the frequency is slowly increased, the intensity at Q will fluctuate, as the interference changes between destructive and constructive.

**Figure 16.33** 

\* For a person with normal hearing, the faintest sound that can be heard at a frequency of 400 Hz has a pressure amplitude of about  $6.0 \times 10^{-5}$  Pa. (This is a very faint sound and the displacement and pressure amplitudes are very small.) At 20 °C for this sound wave (At 20 °C, note that the bulk modulus for air is  $1.42 \times 10^5$  Pa and v = 344 m/s), calculate

- (a) the intensity;
- (b) the sound intensity level; (defined as ten times the logarithm in base 10 with  $I_0 = 1 \times 10^{-12} \text{ W/m}^2$ )  $\beta = (10 \text{ dB}) \log_{10}(I/I_0)$ .
- (c) the displacement amplitude.

Solution (a): Note that the pressure amplitude  $p_m$  and displacement amplitude  $A_m$  are related by

$$p_m = \rho v^2 k A_m = Bk A_m = \left(\frac{2\pi f}{v}\right) BA_M = \omega A_m B/v.$$

In addition, the intensity

$$I = \frac{1}{2}\rho\nu\omega^{2}A_{m}^{2} = \frac{1}{2}\rho\nu\left(\frac{p_{m}\nu}{B}\right)^{2} = \frac{1}{2}\rho\nu\frac{p_{m}^{2}B}{B^{2}\rho} = \frac{\nu p_{m}^{2}}{2B}$$
$$= \frac{344\text{m/s}(6.0 \times 10^{-5})^{2}\text{Pa}^{2}}{2 \times 1.42 \times 10^{5}Pa} = 4.4 \times 10^{-12} \text{ W/m}^{2}$$

Solution (b): 
$$\beta = (10 \text{ dB}) \log_{10} \left( \frac{I}{I_0} \right) = (10 \text{ dB}) \log_{10} (4.4) = 6.4 \text{ dB}$$

**Solution (c):** From above relation, one gets

$$A_m = \frac{vp_m}{2\pi fB} = 5.8 \times 10^{-11} \text{ m},$$

which is very small size in length.

- \* A police car's siren emits a sinusoidal wave with frequency  $f_s = 300$  Hz. The speed of sound is 340 m/s and the air is still.
- (a) Find the wavelength of the waves if the siren is at rest.
- (b) Find the wavelengths of the waves in front of and behind the siren if it is moving at **30** m/s.

**Solution** (a): In this part there is no Doppler effect because neither source nor listener is moving with respect to the air, thus the formula  $v = \lambda f$  gives the wavelength. When the source is at rest,

$$\lambda = \frac{v}{f_s} = 1.13 \text{ m}.$$

**Solution** (b): The wavelength is shorter in front of the siren and longer behind it according to the Doppler effect. In front of the siren and behind the siren, we find

$$\lambda_{\text{in front}} = \frac{v - v_s}{f_s} = 1.03 \text{ m/s}, \qquad \lambda_{\text{behind}} = \frac{v + v_s}{f_s} = 1.23 \text{ m/s}.$$

\* Dune On the planet Arrakis (also known as Dune and featured in the Dune series of novels by Frank Herbert), a male ornithoid is flying toward his friend at 25.0 m/s while singing at a frequency of 1200 Hz. If the stationary female hears a tone of 1240 Hz, what is the speed of sound in the atmosphere of Arrakis?

**Identify:** Apply the Doppler shift equation 
$$f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S$$
.

Set Up: The positive direction is from listener to source.  $f_S = 1200 \text{ Hz}$ .  $f_L = 1240 \text{ Hz}$ .

Execute: 
$$v_L = 0$$
.  $v_S = -25.0$  m/s.  $f_L = \left(\frac{v}{v + v_S}\right) f_S$  gives

$$v = \frac{v_S f_L}{f_S - f_L} = \frac{(-25 \text{ m/s})(1240 \text{ Hz})}{1200 \text{ Hz} - 1240 \text{ Hz}} = 780 \text{ m/s}.$$

Evaluate:  $f_L > f_S$  since the source is approaching the listener. QED.

- \* \* Moving Source vs. Moving Listener.
- (a) A sound source producing **1.00-kHz** waves moves toward a stationary listener at one-half the speed of sound. What frequency will the listener hear?
- (b) Suppose instead that the source is stationary and the listener moves toward the source at one-half the speed of sound. What frequency does the listener hear? How does your answer compare to that in part (a)? Explain on physical grounds why the two answers differ.

<u>Comments:</u> It is the velocity of the source and listener relative to the air that determines the effect, not the relative velocity of the source and listener relative to each other.

#### **Solution:**

**Identify:** Apply 
$$f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S$$
.

Set Up:  $f_S = 1000$  Hz. The positive direction is from listener to source. v = 344 m/s.

#### **Execute:**

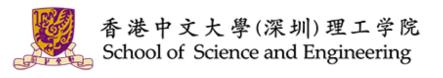

(a) 
$$v_S = -(344 \text{ m/s})/2 = -172 \text{ m/s}, v_L = 0.$$

$$f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S = \left(\frac{344 \text{ m/s}}{344 \text{ m/s} - 172 \text{ m/s}}\right) (1000 \text{ Hz}) = 2000 \text{ Hz}.$$

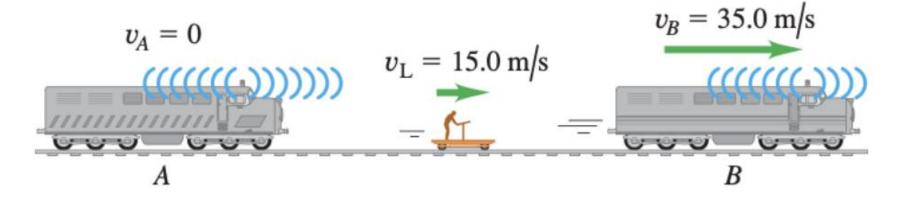

(b) 
$$v_S = 0$$
,  $v_L = +172$  m/s.

$$f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S = \left(\frac{344 \text{ m/s} + 172 \text{ m/s}}{344 \text{ m/s}}\right) (1000 \text{ Hz}) = 1500 \text{ Hz}.$$

**Evaluate:** The answer in (b) is much less than the answer in (a). It is the velocity of the source and listener relative to the air that determines the effect, not the relative velocity of the source and listener relative to each other.

\* \* Two train whistles, **A** and **B**, each have a frequency of **392 Hz**. **A** is stationary and **B** is moving toward the right (away from **A**) at a speed of **35.0 m/s**. A listener is between the two whistles and is moving toward the right with a speed of **15.0 m/s** (Figure below). No wind is blowing.

#### **Questions:**

- (a) What is the frequency from **A** as heard by the listener?
- (b) What is the frequency from **B** as heard by the listener?
- (c) What is the beat frequency detected by the listener?

香港中文大學(深圳)理工学院 School of Science and Engineering

**Identify:** Apply the Doppler shift equation  $f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S$ .

**Set Up:** The positive direction is from listener to source.  $f_S = 392$  Hz.

#### **Execute:**

(a)  $v_S = 0$ ,  $v_L = -15.0$  m/s.

$$f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S = \left(\frac{344 \text{ m/s} - 15.0 \text{ m/s}}{344 \text{ m/s}}\right) (392 \text{ Hz}) = 375 \text{ Hz}.$$

(b)  $v_S = +35.0 \text{ m/s}, v_L = +15.0 \text{ m/s}.$ 

$$f_L = \left(\frac{v + v_L}{v + v_S}\right) f_S = \left(\frac{344 \text{ m/s} + 15.0 \text{ m/s}}{344 \text{ m/s} + 35.0 \text{ m/s}}\right) (392 \text{ Hz}) = 371 \text{ Hz}.$$

(c)  $f_{\text{beat}} = f_1 - f_2 = 4 \text{ Hz}.$ 

Evaluate: Distance between whistle **A** and listener is increasing, and for whistle **A**  $f_L < f_S$ ; Distance between whistle **B** and listener is also increasing, and for whistle **B**  $f_L < f_S$ .

QED. Gao Qian

### \* \* (Halliday C17-P31)

As shown in figure below, a French submarine and a U.S. submarine move toward each other during maneuvers in motionless water in the North Atlantic. The French sub moves at the speed  $v_F = 48.00 \text{ km/h}$ , and the U.S. sub at  $v_{US} = 72.00 \text{ km/h}$ . The French sub sends out a sonar signal (sound wave in water) at  $1.560 \times 10^3 \text{ Hz}$ . Sonar waves travel at 5470 km/h.

#### **Questions:**

- (a) What is the signal's frequency as detected by the U.S. sub?
- (b) What frequency is detected by the French sub in the signal reflected back to it by the U.S. sub?

#### **Solution:**

(a) The frequency as detected by the U.S. sub is

$$f_1' = f_1 \left( \frac{v + v_{US}}{v - v_F} \right) = (1.560 \times 10^3 \text{ Hz}) \left( \frac{5470 \text{ km/h} + 72.00 \text{ km/h}}{5470 \text{ km/h} - 48.00 \text{ km/h}} \right) = 1.595 \times 10^3 \text{ Hz}.$$

(b) If the French sub were stationary, the frequency of the reflected wave would be

$$f_r = f_1(v + v_{US})/(v - v_{US}).$$

Since the French sub moving toward the reflected signal with speed  $v_F$ , then

$$f'_r = f_r \left( \frac{v + v_F}{v - v_F} \right) = f_1 \frac{(v + v_F)(v + v_{US})}{(v - v_F)(v - v_{US})}$$

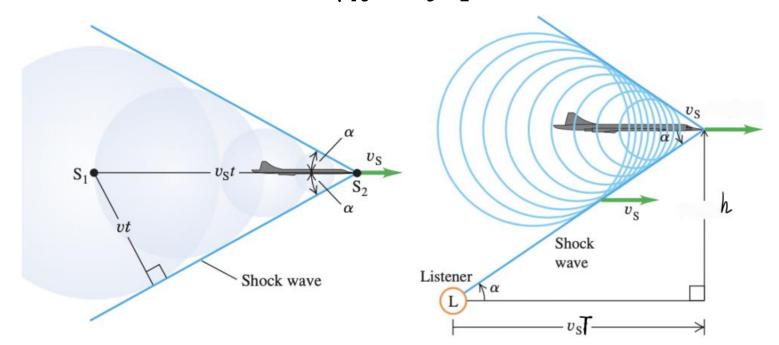

$$= (1.560 \times 10^3 \text{ Hz}) \frac{(5470 + 48.00)(5470 + 72.00)}{(5470 - 48.00)(5470 - 72.00)} = 1.630 \times 10^3 \text{ Hz}.$$

### \* \* Supersonic Shock Waves.

On a clear day you see a jet plane flying overhead. From the apparent size of the plane, you determine that it is flying at a constant altitude h. You hear the sonic boom at time T after the plane passes directly overhead. Show that if the speed of sound v is the same at all altitudes, the speed of the plane  $v_s$  is

$$v_S = \frac{hv}{\sqrt{h^2 - v^2 T^2}}.$$

#### **Solution:**

(1) In the case of supersonic shock wave, from above figures and geometry, one gets

$$\sin \alpha = \frac{v}{v_S}$$
, (left figure) and  $\tan \alpha = \frac{h}{v_S T}$ . (right figure)

(2) Then use the trigonometric identity which relates  $\sin \alpha$  to  $\tan \alpha$ , one finds

$$\tan \alpha = \frac{\sin \alpha}{\sqrt{1 - \sin^2 \alpha}} = \frac{v}{\sqrt{v_S^2 - v^2}} = \frac{h}{v_S T}.$$

- (3) In the end, one can solve for  $v_S$  and find it is given by  $v_S = \frac{hv}{\sqrt{h^2 v^2 T^2}}$ .
- (4) For a given h, the faster the speed  $v_S$  of the plane, the greater is the delay time T. The maximum delay time is h/v as expected when  $v_S \to \infty$ .
